

## ThinCert™ Cell Culture Inserts

### List of Peer-reviewed Publications

This document provides a list of studies which all have been conducted using ThinCert™ cell culture inserts and published after peer-review.

Listed publications are categorized according to their fields of application:

1. Co-culture studies
2. Migration and invasion studies
3. Transport, uptake, permeability, polarized growth
4. Skin models, organotypic culture, 3D culture
5. Infection studies and others

#### 1. Co-culture studies

Co-culture describes various techniques where different cell populations are cultivated in close proximity in the same cell culture environment. The applications of co-cultures are multifaceted and include the stimulation and maintenance of cell function and differentiation, the cultivation of embryonic stem cells on feeder cells, investigations of immune cell interactions, infections studies and studies on paracrine interactions. Direct co-culture can be performed in nearly all cell culture dishes, for instance by layering two cell types one on top of the other. In contrast, indirect co-culture takes advantage of ThinCert™ cell culture inserts with porous membranes, to keep co-cultivated cell populations separated.

## 2. Migration and invasion studies

The filter assay is one of the most frequently used assays for studying cell migration. First published in 1962 by Stephen Boyden, this assay is still employed in cell migration studies. The filter assay involves a two-compartment system where cells may be induced to migrate from an upper compartment through a porous membrane into a lower compartment, thus following the gradient of a chemoattractant. Modifications of the filter assay include variants where the porous membrane is coated with an extra-cellular matrix (invasion assays), or where it carries a cell monolayer (transepithelial migration assays).

### **3. Transport, Uptake, Permeability, Polarized Growth**

ThinCert™ cell culture inserts with porous membrane supports are widely accepted tools for the reconstruction of functional epithelia and tissues in vitro. In cell culture inserts, high density cell populations may be achieved with nourishment from two different areas: the surface that faces the porous membrane support as well as the one that faces away. This dual nutrient access, along with the presence of a solid substrate that may carry components of the ECM has proven to be an indispensable stimulus to establish polarity in cultivated epithelia. Reconstructed epithelia may be exploited to study transepithelial vectorial transport, substance uptake and permeability.

## 4. Skin Models, organotypic culture, 3D culture

For many years live-animal experimentation provided the singular means to access intact and living tissue for biological and pharmaceutical research. This situation changed with the introduction of new cell culture approaches that enabled reconstruction of tissue by multi-layering individual cell types *in vitro*. Such approaches typically involve the use of porous membrane supports and/or three-dimensional collagen gels to re-create *in vivo*-like growth within a cell culture environment. With the availability of primary cells from biopsies and organ donations, the spectrum of reconstructed tissues may be expanded to additionally include human material. Today, reconstructed renal and intestinal epithelia, epidermis, full thickness skin, airway epithelia, cornea and oral epithelia are frequently used to assess corrosive, irritating and phototoxic potential of substances as well as to study drug delivery and pathology.
